

SUMMARY OF VITAL STATISTICS 2002

THE CITY OF NEW YORK

Michael R. Bloomberg, Mayor

Thomas R. Frieden, M.D., M.P.H. Commissioner

Kelly Henning, M.D., Director, Division of Epidemiology

SUMMARY OF VITAL STATISTICS 2002 THE CITY OF NEW YORK

Bureau of Vital Statistics
New York City Department of Health and Mental Hygiene

Steven Schwartz, Ph.D., Registrar and Assistant Commissioner

Wenhui Li, Ph.D., Research Scientist

DECEMBER 2003

This report was prepared by the Statistical Analysis and Reporting Unit of the Bureau of Vital Statistics: Wenhui Li, PhD, Darlene Kelley, and Joseph Kennedy. The data are derived from vital event certificates filed with and processed by the staff of the Offices of Vital Records and Vital Statistics.

This publication is available at www.nyc.gov/health.

2001	8,008,278	Excluding World Trade Center disaster deaths				60,218	7.5		
2002	8,008,278	122,937	15.4	65,490	8.2	59,651	7.4	742	6.0

Note: Figures for single years prior to 1956 appear in the annual summaries for 1965 and earlier. Figures for 1898-1913 births are estimated.

Intercensal counts are interpolated; the interpolation from 1990 to 2000 uses an exponential formula. See Technical Notes.

* Total number of reported deaths is preliminary due to incomplete reporting of World Trade Center (WTC) disaster deaths. As of October 31, 2003, 2,746 deaths from WTC disaster were reported. See Special Section for detailed statistics on WTC deaths.

* These population figures replace those published in the 2001 Summary of Vital Statistics, and are based on the Census Bureau's modification of its data correcting the reporting on race items. The major effects are a reduction of 65% in the total for Other and Multiple Race and increases of 3%, 3%, and 6% for Non-Hispanic White, Non-Hispanic Black, and Asian and Pacific Islander, respectively. There were no modifications for age and sex. See Technical Notes.

32.# Complications of medical and surgical care (Y40-Y84, Y88)	36	9	9	8	3	2	4	1	14	22	
33.# Operations of war and their sequelae (Y36,Y89.1)	1	—	—	—	—	—	1	—	1	—	

Note: Beginning January 1, 1999 all causes were coded using ICD-10. The comparability ratio represents the net effects of changing from ICD-9 to ICD-10 for the selected cause or group of causes. (The preliminary comparability ratios are based on a nonrandom national sample of over 1.8 million 1996 death certificates processed by NCHS; final data, based on 2.3 million deaths, are not yet available.) See the Technical Notes on Cause-of-Death Coding.

Motor vehicle accident codes include V02-V04, V09.0, V09.2, V12-V14, V19.0-V19.2, V19.4-V19.6, V20-V79, V80.3-V80.5, V81.0-V81.1, V82.0-V82.1, V83-V86, V87.0-V87.8, V88.0-V88.8, V89.0, V89.2.

* Excludes deaths occurring more than 42 days after the termination of pregnancy, and includes obstetrical tetanus. See Technical Notes.

Eligible to be ranked as leading causes nationally and in New York City. Several causes were added to this list in 2000; they are of relatively low frequency in New York City and do not affect rankings of leading causes in 1999 or 2000.

Three cause groups are treated differently in New York City than they are nationally. Mental and behavioral disorders due to use of alcohol and mental and behavioral disorders due to use of psychoactive substance excluding alcohol and tobacco are eligible to be ranked as leading causes in New York City because of the number of deaths and their public health importance. Accidental deaths are ranked without those due to poisoning by psychoactive substances excluding alcohol and tobacco.

Table 5.

Leading Causes of Death* in Specified Age Groups by Sex
New York City, 2002

Rank	ALL AGES	Male		Female		All	
		Deaths	Percent	Deaths	Percent	Deaths	Percent

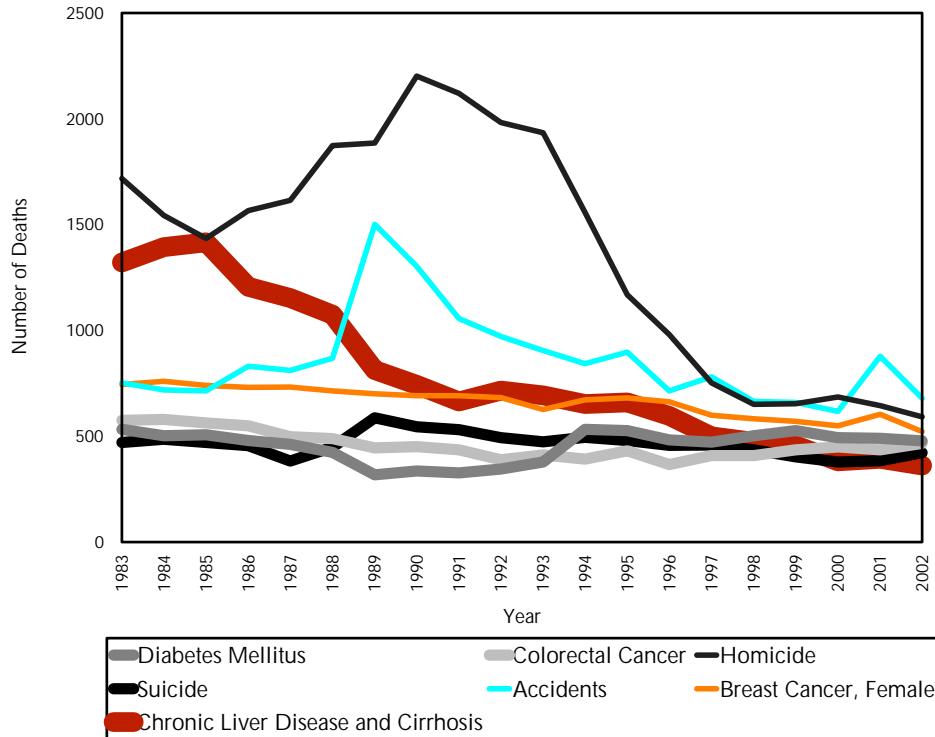

Figure 1. Number of Deaths from Selected Causes
Age < 65, New York City, 1983-2002

The number of homicide deaths in New York City declined steadily between 1990 and 1998, and again between 2000 and 2002 after a small rise from 1998 to 2000. Suicide deaths declined slightly in the last two decades, from 471 in 1983 to 422 in 2002; suicide deaths peaked in 1989. The number of colorectal cancer deaths among age < 65 decedents also declined in the past two decades, from 575 to 466.

The surge of accidental deaths in 2001 was caused by the Flight 587 air crash.

The Ninth Revision of the International Classification of Diseases (ICD-9) was used to code causes of death in 1979-1998. ICD-10 was implemented in 1999. The preliminary comparability ratios for the ICD-9 to ICD-10 conversion are listed in Table 4.

All reported WTC deaths are homicides and not included in this graph for the year 2001. See Special Section for detailed statistics on WTC deaths.

See Figure 5 and 6 for comparable graphs for all ages, and Figure 8 for deaths due to HIV diseases.

Note: The ten leading causes of death in each ethnic group for both sexes combined are arranged in decreasing order of frequency.

Totals may not equal 100% due to rounding. Decedents of other and unknown ethnicities are not shown.

*Beginning January 1, 1999 all causes were coded using ICD-10. See Table 4 for preliminary comparability ratios.

Table 8. Deaths and Death Rates per 100,000 Population from Selected Causes* by Community District of Residence, New York City, 2002 (Continued)

Community District	Population 2000 Census	All Causes (Rate per 1,000)		Heart Diseases		Malignant Neoplasms		HIV Disease		Influenza and Pneumonia		Cerebro-Vascular Diseases		Chronic Lower Respiratory Diseases		Chronic Liver Disease & Cirrhosis		Diabetes Mellitus		Mental Disorders due to Substance & Accidental Poisoning		Accidents Except Drug Poisoning		Intentional Self-harm (Suicide)		Assault (Homicide)		Events of Undetermined Intent

Note: Borough populations, which are county census figures, do not equal the sum of the community district populations, which are based on service delivery areas. See the Technical Notes for a discussion of the number, construction and names of community districts. Non-residents and residence unknown are not shown.

* Beginning January 1, 1999 all causes were coded using ICD-10. See the Technical Notes for cause-of-death coding.

Borough totals may be higher than the sum of the community districts, as they may include some deaths whose community district could not be determined.

Table 9.

Deaths by Place of Death
New York City, 1992 - 2002

Note: For 1983-1986, only AIDS was recognized as a cause of death and coded 279.1; from 1987 through 1998, AIDS was coded 042 and other HIV diseases were coded 043-044.

Under ICD-10, beginning in 1999, HIV disease is coded to B20-B24. In 1982, 30 deaths were attributed to AIDS.

Tables showing deaths due to AIDS alone for 1983-1996 can be found in the Vital Statistics Summaries for 1987-1996.

* Beginning January 1, 1999 all causes were coded using ICD-10. See the Technical Notes for a discussion of HIV disease and AIDS as the cause of death.

Note: Three year (1999-2001) death data are used to estimate 2000 life expectancy to smooth the outcome. Life expectancy figures for 1990 are recalculated by using same methodology as 2000 and therefore the numbers are slightly different from the 1999 and earlier reports. See Technical Notes.

* World Trade Center (WTC) disaster deaths are not included. See Special Section for the impact of WTC deaths on life expectancy in New York City.

Note: Rates for 1979-1981, 1989-1991, and 1999-2001 are based on deaths to New York City residents only, regardless of place of occurrence, while those for previous years included all events in New York City, regardless of the residence of the decedents.

For 1901-1903 and 1909-1911 rates are adjusted for age and sex. For years before 1999, rates are adjusted for age, sex and race (white and others). Standard is United States population, 1940.

* Data are not available or not applicable.

** For 1999-2001 rates are adjusted only for age. A 2000 US standard population is used to calculate age-adjusted death rates. WTC deaths are not included. See Technical Notes.

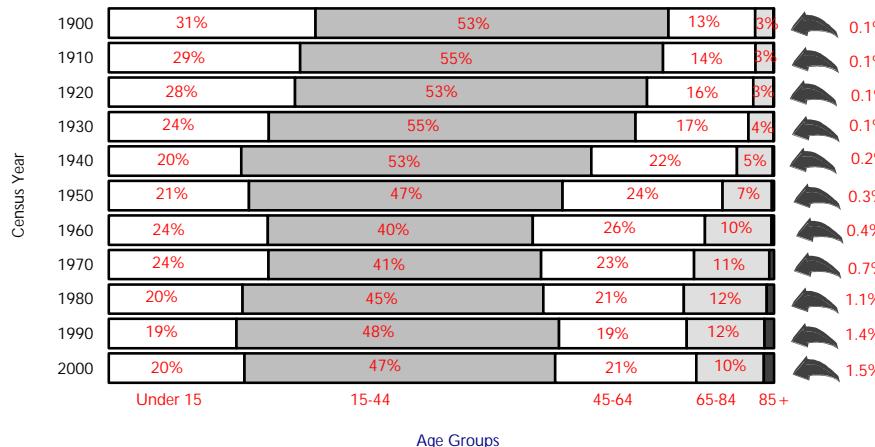

Figure 2. Age Composition of the Population
New York City, 1900-2000

The changing age composition of the City reflects changes in life expectancy as well as natural historic trends. The effect of the economic depression of the 1930s on the number of live births is seen in the lower percentage of residents under age 15 in 1940, while the post-World War II baby boom increased this segment rapidly after 1950. From 1900 to 2000, the proportion of residents age 45 and over doubled, from 16% to 32%, with the greatest increase among those 85 and over. From 1990 to 2000, the proportion of residents age 65 to 84 declined 4%, while the proportion 85 and over increased 19%. Over this ten-year period, the median age of city residents increased from 33.7 to 34.2 years.

Figure 3. Age-Sex Composition of the Population
New York City, 2000

This age-sex pyramid shows each age-sex group as a percent of the total population. There are more females than males overall, 53% to 47%, and more females in every age group over 19. The difference is the greatest among those 85 and over, where there are two and one-half times as many women as men. The smaller segment of both males and females in age group 10-14 and 15-19 reflect the lower number of births in the 1980s, compared to births in the first half of the 1990s.

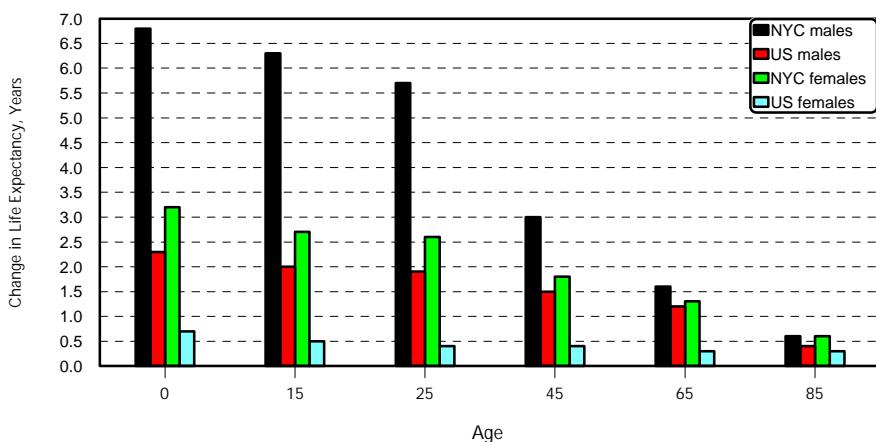

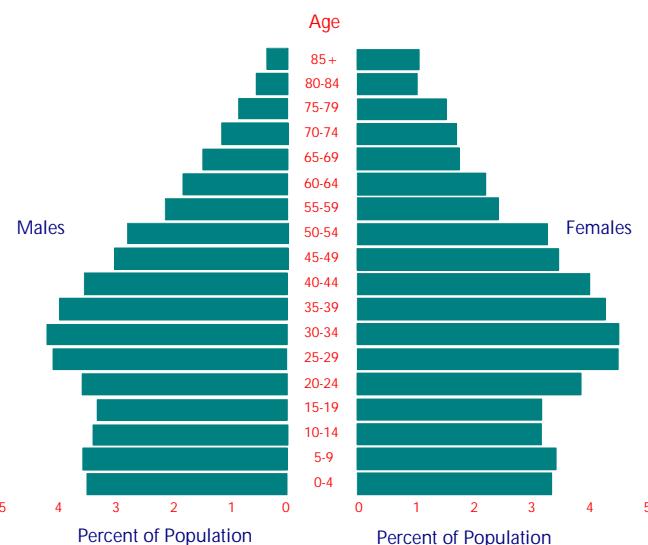

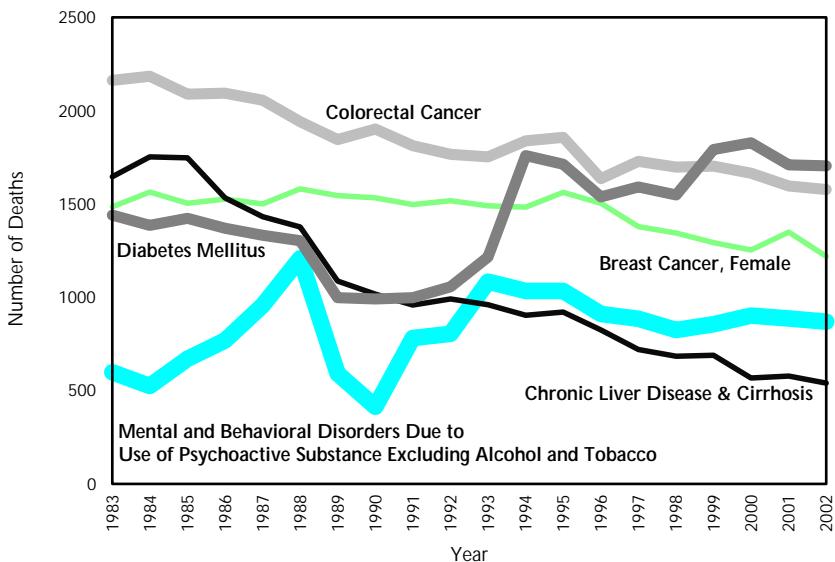

Figure 4. Changes in Life Expectancy at Selected Ages
by Sex, 1990 and 2000
New York City and United States

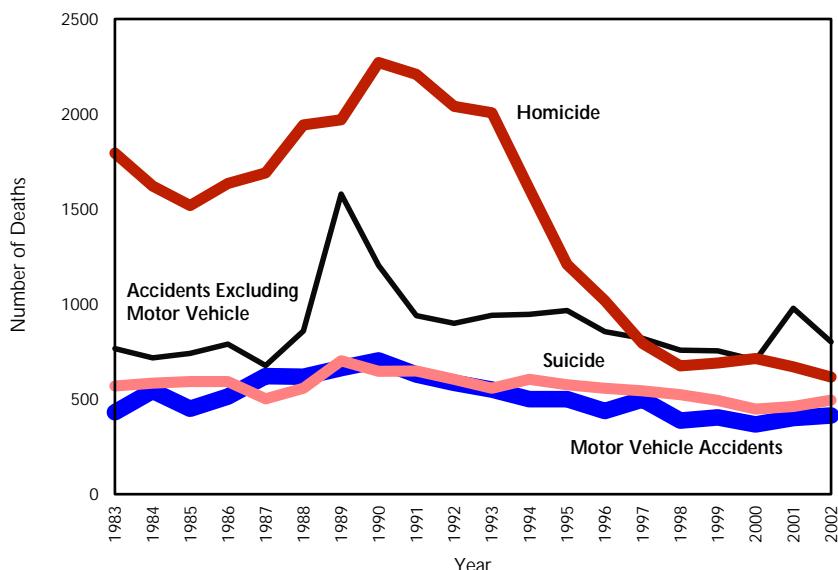

Between 1990 and 2000, in contrast to the prior decade, life expectancy for male New York City residents at birth, at ages 15 and 25 increased substantially. The increases are 6.8, 6.3, and 5.7 years respectively. Contributing factors include declines in infant mortality, HIV, and homicide deaths. Life expectancy for all United States males at these ages also increased but at lower rates, from 1.9 to 2.3 years. Life expectancy for New York City females increased more than for all United States females. At selected older ages New York City male residents also showed greater increases in life expectancy than did males nationwide but not as much as younger ages. Nationwide, females had a small increase in life expectancy at all ages.
Note: Calculations exclude World Trade Center deaths.

**Figure 5. Number of Deaths from Selected Natural Causes
New York City, 1983-2002**

The number of colorectal cancer deaths declined in the past two decades, from 2,161 to 1,577. The number of women died from breast cancer had stayed at 1,500 level until 1997 when the number started to decrease. In 2002 the number was 1,218. The number of chronic liver disease and cirrhosis deaths had a steady decline except during 1984 and 1985. Deaths from diabetes mellitus declined in 1980's, but had a surge in the beginning of 1990's, then have stayed at that level for past several years.

The Ninth Revision of the International Classification of Diseases (ICD-9) was used to code causes of death in 1979-1998. ICD-10 was implemented in 1999. The preliminary comparability ratios for the ICD-9 to ICD-10 conversion are listed in Table 4.

**Figure 6. Number of Deaths from Selected External Causes
New York City, 1983-2002**

The number of homicide deaths in New York City declined steadily between 1990 and 1998, and again between 2000 and 2002 after a small rise from 1998 to 2000. Overall, homicide deaths dropped about two-thirds since they peaked in 1990. Suicide deaths declined slightly in the last two decades, from 570 in 1983 to 495 in 2002; suicide deaths peaked in 1989.

The surge of accidental deaths in 2001 was caused by the Flight 587 air crash. 265 deaths from the crash are included in the total accidental deaths.

The Ninth Revision of the International Classification of Diseases (ICD-9) was used to code causes of death in 1979-1998. ICD-10 was implemented in 1999. The preliminary comparability ratios for the ICD-9 to ICD-10 conversion are listed in Table 4.

All reported WTC deaths are homicides and not included in this graph for the year of 2001. See Special Section for detailed statistics on WTC deaths.

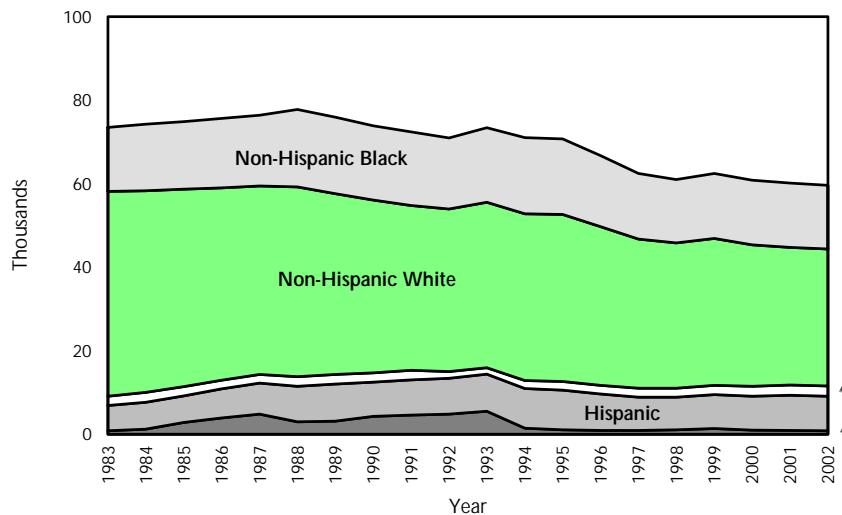

Figure 7. Deaths by Ethnic Group of Decedents
New York City, 1983-2002

The number of deaths from 1983 to 2002 declined 19%, from 73,544 to 59,651, and declined 23% from the peak number of deaths in this period, 77,817 in 1988. However, the number of deaths among Hispanics is about 36% greater in 2002. The number of deaths among non-Hispanic blacks is about the same in 2002 as in 1983 and the number of deaths among Asians is 9% higher than it was in 1983; most of the overall decline is accounted for by the decline in non-Hispanic white deaths of over 30% as this population group declined 24%. WTC deaths are not included in this graph for the year 2001.

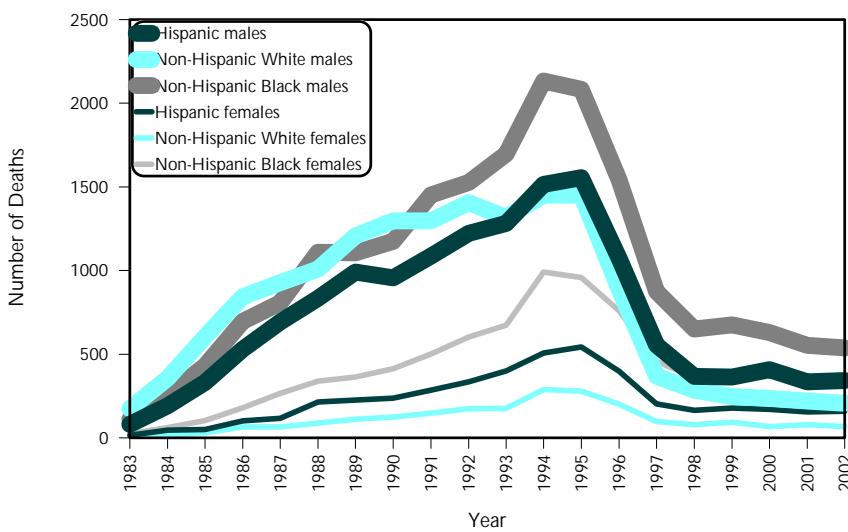

Figure 8. Deaths Due to HIV Disease
by Sex and Selected Ethnic Group
New York City, 1983-2002

The number of deaths due to HIV disease decreased 3.5% from 2001 to 2002 to 1,712, comparable to the 1985 level before it peaked at 7,102 in 1994. The number of deaths among non-Hispanic whites and non-Hispanic blacks decreased from 2001 to 2002 but increased slightly among Hispanics. The possible effect of changes between ICD- 9 and ICD-10, in 1999, have not been analyzed. See the Technical Notes for a discussion of HIV disease and AIDS as a cause of death.

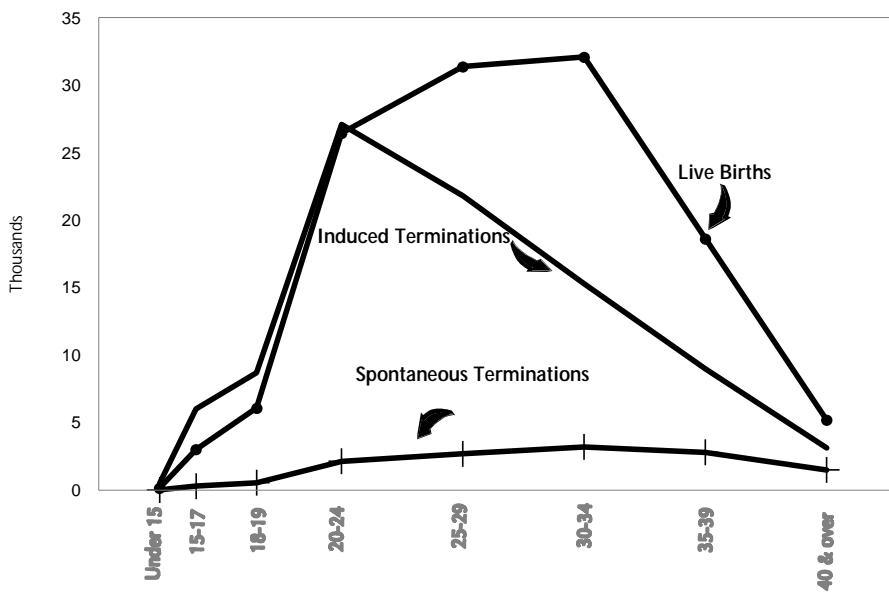

Figure 9. Live Births, Induced Terminations and Spontaneous Terminations of Pregnancy by Age of Woman
New York City, 2002

Over 228,000 pregnancy outcomes were reported in New York City in 2002. About 54% were live births, 40% were induced terminations, and the remainder were spontaneous terminations (fetal deaths). The proportion of pregnancies ending in an induced termination is highest among younger women, and stabilizes at around 30% at age 30. For women under the age of 25, the pregnancy outcome is more likely to be an induced termination than a live birth or spontaneous termination.

The number of induced and spontaneous terminations reported to the Department of Health and Mental Hygiene depends to some extent on active surveillance, notwithstanding that all terminations, not just those of a certain gestational age or weight, are required to be reported.

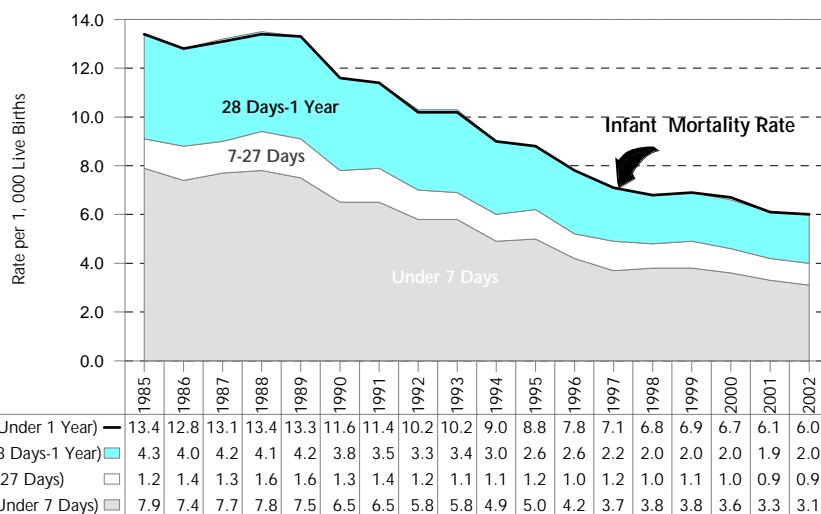

Figure 10. Infant, Neonatal and Post-neonatal Mortality Rates
New York City, 1985-2002

The New York City Infant Mortality Rate continued to decline in 2002, reaching the historic low level of 6.0 deaths per 1,000 live births. Deaths in the early neonatal period after birth (under seven days) declined from 3.3 to 3.1 per 1,000 live births. Late neonatal (seven to twenty-seven days), and post-neonatal deaths (28 days to under one year) IMR stayed at about the same level as 2001. From 1990 to 2002, the rates of both early neonatal deaths and post-neonatal deaths declined by about half, while the rate for late neonatal deaths declined by about 30 percent.

Table 29a. Induced Terminations of Pregnancy by Woman's Marital Status, Age, and Ethnic Group
New York City, 1993 - 2002

	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002

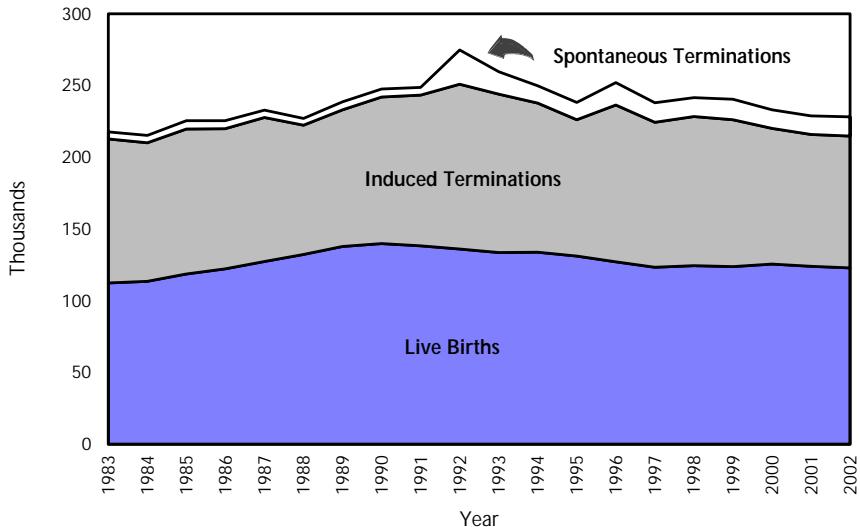

Figure 11. Number of Live Births, Induced Terminations and Spontaneous Terminations
New York City, 1983-2002

The number of live births increased in the 1980s and reached a peak in 1990 during last two decades. Since then the number has been declining at a slow pace. The number of induced terminations had a similar pattern except its peak was 1992. The number of spontaneous terminations also peaked in 1992.

The number of induced and spontaneous terminations reported to the Department of Health and Mental Hygiene depends to some extent on active surveillance, notwithstanding that all terminations, not just those of a certain gestational age or weight, are required to be reported. Increased active surveillance caused a sustained increase in the number of spontaneous terminations reported, beginning in 1992.

**Figure 12. Live Births by Mother's Ethnic Group
New York City, 1983-2002**

The total number of live births registered in New York City rose about 24%, from 112,353 in 1983 to 139,630 in 1990, the highest number since 1970. After 1990, live births declined 12%. Since 1990, there were more births to Hispanic women than to women of any other ethnic group although births to Puerto Rican women declined. Births to both non-Hispanic black and non-Hispanic white women peaked in 1989; by 2002 births to non-Hispanic white mothers declined 7%, and to non-Hispanic black mothers declined 29%. From 1983 to 2002, births to Asian and Pacific Islander women increased 72%, while the population of Asian and Pacific Islanders increased from about 230,000 in 1980 to over 489,000 in 1990 and 827,000 in 2000, a 2.6 fold increase.

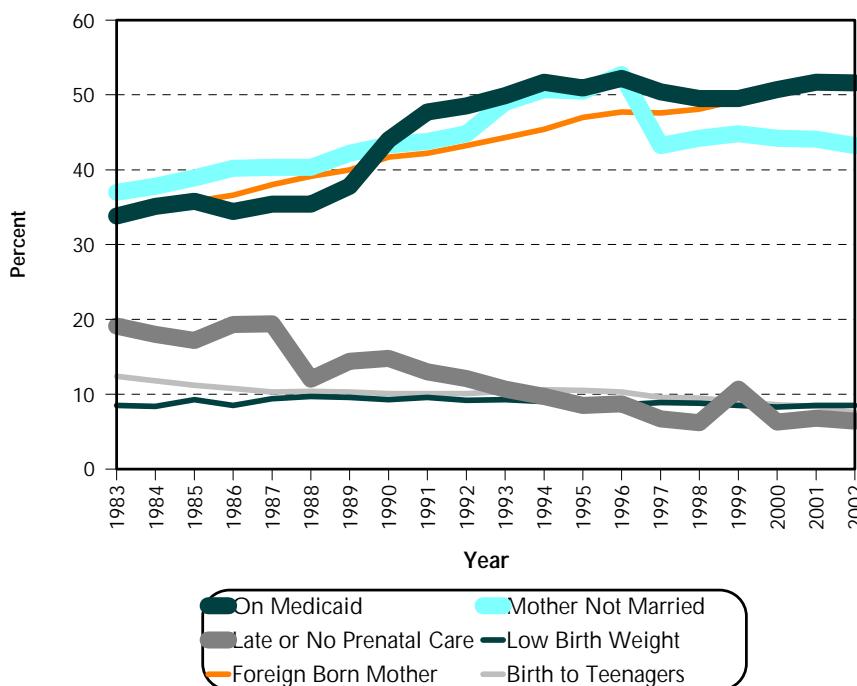

Figure 13. Percent of Live Births with Specified Characteristics, New York City, 1983-2002

The percent of live births to foreign born mothers increased steadily in the last two decades, from 34.0 in 1983 to 52.0 in 2002, reflecting the inflow of new immigrants. The percent of mothers on Medicaid when they delivered their babies surged during the late 80s and early 90s. The percent of low birth weight has been virtually flat for the past 20 years. The percent of late or no prenatal care had a downward trend, from 19.1 in 1983 to 6.4 in 2002. Percent of mothers not married when they had a birth increased from 1982 to 1996. Note that the method used to compute mother's marital status was changed in 1997. As a result, unmarried mothers declined 19.2% in a sample tested by using both old and new methods. See the Special Note On Mother's Marital Status, Summary of Vital Statistics, 1997, pp.32-33. The percent of mothers not married decreased again since 1999, largely due to the decline of teenage mothers who are more likely to be not married.

Eligible to be ranked as leading causes nationally and in New York City. See the Special Note.

Contain causes eligible to be ranked as a leading cause nationally but infrequent in New York City; these created groups permit recognition of important causes of infant deaths.

* Ethnic group is defined by mother's information on the infant's birth certificate. However, in the absence of a matching birth certificate for an infant death, the information on the death certificate is used to assign a maternal ethnic group.

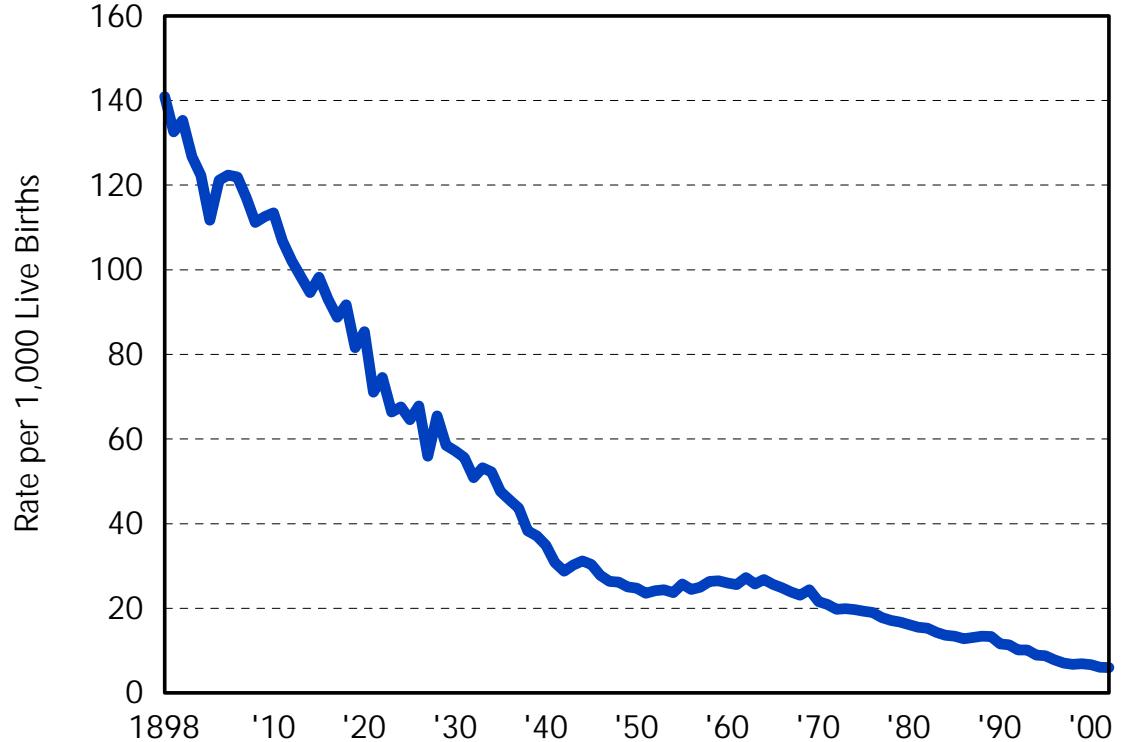

Figure 14. Infant Mortality Rate

New York City, 1898 - 2002

New York City took its present form in 1898 when its boundaries were extended to include all five boroughs: Manhattan, Bronx, Brooklyn, Queens and Staten Island. The infant mortality rate at that time is estimated at 136.7 deaths under one year of age per 1,000 live births, (Because of incomplete reporting of early neonatal deaths, this is almost certainly an underestimate.) Improvements in food and water safety in the earlier part of the twentieth century, and in access to medical care advances in recent years, have contributed to the decline to 6.0 deaths per 1,000 live births in 2002, an historic low.

Rates and Ratios Defined

The numerators of the rates in these tables are events occurring in New York City and reported during the year, unless otherwise specified. The denominator is the resident population figure from the 2000 census, including all ages and both sexes, unless otherwise specified.

Live Birth Rate - The number of live births per 1,000 population.

$$\frac{\text{Live Births} \times 1,000}{\text{Population}}$$

Marriage Rate - The number of marriages per 1,000 population.

$$\frac{\text{Marriages} \times 1,000}{\text{Population}}$$

Infant Mortality Rate - The number of infant (under one year of age) deaths per 1,000 live births.

Neonatal Mortality Rate - The number of neonatal (under 28 days) deaths per 1,000 live births.

Post Neonatal Mortality Rate - The number of post-neonatal (28 days to under one year of age) deaths per 1,000 live births.

$$\frac{\text{Infant Deaths} \times 1,000}{\text{Live Births}}$$

Fetal Death Ratio - The number of fetal deaths of 28 weeks gestation and over per 1,000 live births.

$$\frac{\text{Fetal Deaths 28 Weeks and Over} \times 1,000}{\text{Live Births}}$$

Perinatal Mortality Ratio - The number of fetal deaths of 28 weeks gestation and over plus the number of early neonatal (under seven days) deaths per 1,000 fetal deaths of 28 weeks gestation and over plus live births.

$$\frac{(\text{Fetal Deaths 28 Weeks and Over} + \text{Infant Deaths Under 7 Days}) \times 1,000}{\text{Fetal Deaths 28 Weeks and Over} + \text{Live Births}}$$

Death Rate, all causes - The number of deaths per 1,000 population.

$$\frac{\text{Deaths All Causes} \times 1,000}{\text{Population}}$$

Death Rate, specified causes - The number of deaths due to a specified cause per 100,000 population.

Death Rate, age and sex specific - The number of deaths of persons of specified age and sex per 1,000 population of the specified age and sex.

Death Rate, age, sex and race adjusted - The number of deaths per 100,000 standard population. Age, sex and race specific death rates are applied to a standard population, eliminating the effect of differences in population composition, and allowing comparisons over time or between geographic areas.

Maternal Mortality Ratio - The number of deaths due to complications of pregnancy, childbirth and the puerperium occurring within 42 days of delivery per 100,000 live births.

Special Section: World Trade Center Disaster Deaths

World Trade Center Disaster Deaths

This special section presents preliminary data on the deaths caused by the World Trade Center disaster on the morning of September 11, 2001. The data presented are based on 2,746 death certificates filed with the Office of Vital Records and 3 deaths that occurred outside New York City through October 31, 2003, a little more than two years after the event. Data have been updated according to corrections and amendments submitted by the Medical Examiner's Office and family members. Most of the death certificates were issued in the absence of a body as a result of a court order. When remains are identified, the death certificate is amended to reflect the new information. At the time of publication, the official estimate of WTC deaths is 2,752. Since the death certificates of three people reported missing have not yet been resolved by the courts, the data are still not final.

Demographic information on a decedent is provided by the funeral director, if one was involved, or directly by the family through an affidavit, if no remains were recovered. The manner of death for all of the reported deaths was homicide. Death certificates for the airplane hijackers have not been issued and are not included in these data; these deaths would be classified as suicides if prepared by the Medical Examiner.

The figures and tables below present data on selected demographic and other characteristics of the decedents. Figure WTC1 and Table WTC1 show that the majority of decedents were young men, with modal age 35-39 years. The median ages are 39 for men and 38 for women. Table WTC2 shows that virtually all of the deaths occurred at the time of the attack; only thirteen occurred later than September 11, 2001. Table WTC3 shows that about 29% of decedents were never married and 63% were married or separated. Table WTC4 presents the number of decedents by borough of residence of New York City, New York State counties, other states, and foreign countries. It shows that about 43% of decedents lived in New York City, another 22% lived elsewhere in New York State, and about 34% lived in other places of the United States. Twenty-five percent were residents of New Jersey. A total of 91 decedents were residents of Massachusetts, the origin of the two airplanes that struck the WTC, and 30 were residents of California, the

destination of the flights. Table WTC5 presents that of these 2,749 decedents, 61% were non-Hispanic white males, 15% were non-Hispanic white females, 7% were Hispanic males, 3% were Hispanic females, 5% were non-Hispanic black males, 3% were non-Hispanic black females, 4% were Asian/Pacific Islander males, and 2% were Asian/Pacific Islander females. A total of 1,849, 67% of all decedents, had graduated from college or had some postgraduate education. Table WTC6 presents the birthplace of the decedents (limited to five or more occurrences); while only 1% were residents of foreign countries, 21% were born abroad. About 98% of those killed were at work at the time, as seen in Table WTC7. Tables WTC8 and WTC9 are compiled from the Census of Fatal Occupational Injuries (U.S. Department of Labor, Bureau of Labor Statistics, in cooperation with the New York City Department of Health and Mental Hygiene and State and Federal agencies). Forty-three percent were in managerial and professional specialty occupations, 34% were in technical, sales, and administrative support occupations, and 20% were in service occupations. Eighty-one percent worked for private industry and 19% worked for government at the time of the incident. Among those who worked for private industry, 78% were in the finance, insurance, and real estate industries. Table WTC10 shows the impact of WTC death on the 2000 life expectancy estimation. When WTC deaths were included in 1999-2001 New York City death data, life expectancy at birth decreased by 0.2 year for males. There was no change of life expectancy at birth for females. The biggest change, -0.4 year, was at age 15 for non-Hispanic white males. Figure WTC2 is new and presents the number of births by week, 2000-2002, from which shows no apparent increase or decrease in the number of births 9 months after the attack. The data in Tables WTC11 and WTC12 are from the NYC Office of Chief Medical Examiner (OCME). As of November 10, 2003 the OCME had issued 2,746 death certificates, including 1,530 for victims identified and 1,216 for decedents whose remains had not been found or identified. Methods used to identify decedents by a single modality included DNA 79%, dental radiographs 11%, and fingerprints 5%. Multiple modalities were used to identify 527 decedents, and 1,003 were identified by a single modality.

TECHNICAL NOTES, 2002

VITAL EVENTS - Vital event data reported here are based on occurrences in New York City to both residents and non-residents. Tables that include a geographic breakdown for residents show non-resident and residence-unknown data separately. Where there is no geographic breakdown, all New York City occurrences are included. Counts of births, deaths and induced and spontaneous terminations of pregnancy are based on certificates filed with the Office of Vital Records, New York City Department of Health and Mental Hygiene. Birth certificates are created, printed and filed using the Electronic Birth Certificate (EBC) system. The number of induced and spontaneous terminations of pregnancy reported each year depends to some extent on the level of active surveillance by the Office of Vital Statistics. Some events from earlier years filed too late for inclusion in the year of occurrence are included in each year's annual statistical reports.

! The number of marriages shown in Table 1 and in Table 49 is the number of marriage licenses issued by the City Clerk. Tables 22, 23, and 24 also use outside data sources; see Life Expectancy below. Tables WTC7, WTC8 and WTC9 use data compiled from the Census of Fatal Occupational Injuries (CFOI). See note on World Trade Center Death Data below.

! For public health purposes, the demographic and medical information on the certificates is coded in general agreement with standards developed by the National Center for Health Statistics (NCHS). In some instances, such as ancestry of decedent or mother, New York City data are more detailed.

! Because New York City law prohibits recording mother's marital status on the birth certificate, it is calculated using other items. (See Mother's Marital Status below.)

POPULATION - Population data in the 2000 and subsequent issues of the Vital Statistics Summary are, for the most part, based on data provided by the New York City Department of City Planning (DCP) from the U. S. Census enumeration as of April 1, 2000. Population counts for the city, its boroughs, Health Center Districts, and Community Districts are updated to 2000. Recently, the Census Bureau produced a modified race file (Census 2000 Modified Race Data [MR (31)-CO.txt]). Therefore Table 2 was changed by using modified race population data. The major effects are a reduction of 65% in the total for "Other and Multiple Race" and increases of 3%, 3%, and 6% for "Non-Hispanic White", "Non-Hispanic Black", and "Asian and Pacific Islander", respectively. There was no change for Hispanic population.

In Table 1, the population figures for census years 1960, 1970, 1980, 1990, and 2000 are census counts; for intercensal counts through 1989, straight-line interpolations are used, while the interpolation from 1990 to 2000 uses an expo-

nential formula which assumes that the growth rate was the same through the decade: $\text{pop}(t)/\text{pop}(t_0) = e^{rt}$ (where r is a constant growth rate and t is the interval).

LIFE EXPECTANCY, AGE SPECIFIC AND ADJUSTED DEATH RATES - Life expectancy tables summarize the effect of mortality rates prevailing at a specific time on persons being born or living at that time. Tables may be computed for population subgroups, most often males and females and race groups. The components required are counts and mortality figures for the desired subgroups. Life expectancy tables for New York City are presented for census years, when accurate population data are available. The mortality experience for the census year and for the year before and the year after is used to smooth statistical variation and reduce the large effect an unusual event in a single year can have, such as a flu epidemic or the World Trade Center disaster.

! 1990 Census MARS (modified for age, race, and sex) population and 1989-1991 mortality data were used to calculate 1990 life expectancy, average yearly age-sex-specific death rates for the three years (Table 23), and cause-specific average yearly age-sex-race adjusted death rates (Table 24). 2000 census population data and 1999-2001 mortality data were used to prepare these tables. Adjustment allows comparisons between rates to be made over time or between geographic areas by eliminating the effects of differences in the composition of the populations. For 1999-2001, cause-specific rates are adjusted only for age to avoid losing too much information from crude death rates. A new 2000 US standard population is used to calculate cause-specific age-adjusted death rates while for earlier years the 1940 standard US population was used. Since Census Bureau has not produced MR 2000 data by single year of age, there is no change for life expectancy calculation and age-adjusted death rates..

! A change in the data used for the 1980 and 1990 calculations is noted in Tables 23 and 24 by a line separating these rates from those for earlier years. The calculations for 1980 and 1990 used information on all deaths occurring to New York City residents regardless of place of occurrence (obtained from the New York State Department of Health), whereas previous computations used all deaths occurring in New York City regardless of residence of the decedent. The data were also used to compute 1980 life expectancy tables to facilitate comparisons with 1990 figures. For 2000, mortality data also include all New York City residents regardless of place of occurrence. Mortality data were obtained from NCHS, which may include more non-New York City occurrences than previous years when the data were obtained from New York State. Another line is drawn in Table 24 to show these differences, data source and standard population, between the 1999-2001 period and earlier years.

! 2000 life expectancy was estimated by ethnic

groups instead of race to ascertain differences among Hispanics, non-Hispanic whites and non-Hispanic blacks. To enable comparison, life expectancy was recalculated by ethnic groups for 1990.

! Historical data on Hispanic ancestry and estimates of life expectancy should be used with caution. Before 1993, ancestry of decedents, which may indicate decedents' Hispanic ethnicity, was obtained from the medical certifier. Under-reporting of all ancestries, including Hispanic, was therefore possible. To overcome this problem, death certificates were revised in June 1993 to require funeral directors to provide the ancestry information, presumably from decedents' family members. Hispanic life expectancy may be overestimated because of the age distribution of Hispanics and because of immigration patterns. The age distribution of Hispanics is different from non-Hispanic whites and non-Hispanic blacks, with fewer Hispanics in the older age groups than other ethnic groups. This would cause an underestimate of Hispanic death rates and hence overestimate Hispanic life expectancy. An overestimate of Hispanic life expectancy would also occur if Hispanics moved out of the United States to die at a greater rate than other ethnic groups.

RACE, ANCESTRY, ETHNIC GROUP, AND BIRTHPLACE
Race in the 2000 Census - The 2000 census permitted respondents to describe themselves and household members as being of more than one race, selecting from six race categories: white, black, American Indian and Alaska native, Asian, Native Hawaiian and Other Pacific Islander, and some other race. These categories yield 63 possible combinations. Respondents were also asked if they were of Hispanic origin. The resulting responses could be organized into 64 groups, referred to by the DCP as "mutually exclusive race/Hispanic categories." DCP combined categories into a set of seven: Hispanic origin, non-Hispanic White, non-Hispanic Black, non-Hispanic Asian or Pacific Islander, non-Hispanic American Indian and Alaska Native, non-Hispanic of some other race, and non-Hispanic of two or more races. These categories are equivalent to the vital statistics variable ethnicity (see below), except for the group of two or more races. (Vital statistics data currently collect only a single race.) In Table 2, population data are presented using DCP terminology, "mutually exclusive race and Hispanic origin" with the last three categories combined; the death data presented in Table 3 use the term ethnicity.

Race and Ethnicity in Vital Statistics - Race and ancestry are separate items on the certificates, reported usually by a parent on the birth certificate, and by a relative of the decedent or by the funeral director on the death certificate. Responses are coded in general conformance to rules of NCHS.

! In 1992, five additional codes for Asian and

TECHNICAL NOTES, 2002

Pacific Islander races were added, following their introduction by NCHS: Asian Indian, Guamanian, Korean, Samoan and Vietnamese. Codes already in use included Chinese, Filipino, Hawaiian, Japanese and other.

! The ordered selection rules for ethnic group first assign Puerto Rican or other Hispanic ethnicities based on ancestry, regardless of race. Then, those of other ancestries are classified by race as Asian, non-Hispanic white, non-Hispanic black, other or unknown.

! In certain instances, the item birthplace is used to remove ambiguity in the race item.

! Persons whose race is black and whose ancestry is American are classified as being of African-American ancestry.

! Ancestry is defined by NCHS as the nationality, lineage, or country where the subject's ancestors were born before their arrival in the United States; if a religious group is reported, NCHS instructions are to ask for the country of origin or nationality. In New York City, enough certificates with ancestry reported as Jewish or Hebrew are received to warrant inclusion in these tables, notwithstanding the religious meaning of the terms. An increase in 1999 of about 2,000 in the number of mothers reporting Hebrew or Jewish ancestry resulted from quality assurance discussions with several hospitals that included clarification of the meaning of ancestry. These hospitals replaced the general term American with individual information provided by the patients.

! As the city's immigrant population has increased in recent years, so has interest in birthplace as a demographic variable. Tables on birthplace of decedents and of mothers were added in 2000.

CAUSE OF DEATH - Cause of death information presented is the underlying cause of death on each certificate, selected using rules issued by NCHS and codes of ICD-10, implemented January 1, 1999. Earlier revisions and the year their codes were implemented are the Fifth, 1939; Sixth, 1949; Seventh, 1959; Eighth, 1969; and Ninth, 1979. Long term trends in causes of death should be interpreted with caution because of possible changes in causes and groupings with each revision.

HIV and AIDS Mortality - In ICD-10, deaths due to HIV disease are not divided into AIDS deaths and deaths due to other HIV infections, but are characterized by the resulting disease or condition. HIV deaths (ICD-10 codes B20-B24) are shown in Tables 4, 5, 6, 7, 8, 20, and 21, and Figure 6.

! From 1983 through 1986, AIDS and other HIV deaths were assigned code 279.1. In 1987, NCHS introduced code 042 for AIDS and 043-044 for other HIV deaths, and they were reported this way in Table 3 through 1998. Table 25

contains only AIDS deaths.

! A fuller discussion of the history of HIV coding can be found in the 1997 and 1998 Vital Statistics Summaries.

! The incidence data in Table 48 are provided by the New York City HIV Epidemiology Program. Their active surveillance system identifies persons diagnosed with AIDS, a reportable disease in New York State.

Deaths Due to Drug Abuse - In both ICD-9 and ICD-10, there are two groups of codes that can be used for drug deaths, depending on the information on the death certificate: natural cause codes and external cause codes (overdoses are considered poisoning). The natural cause group in ICD-10, mental and behavioral disorders due to psychoactive substance use excluding alcohol and tobacco (F11-F16, F18-F19) includes psychoses due to drug use and non-dependent drug use, two causes not included in the Vital Statistics Summary reports using ICD-9. Deaths due to alcohol are reported separately; deaths due to tobacco are not reported separately. The poisoning codes for psychoactive substances excluding alcohol and tobacco in ICD-10 (X40-X42, X44) are substantially the same as in ICD-9.

! Revised procedures at the Office of Chief Medical Examiner in 1989 led to a substantial portion of deaths related to drug use being classified as accidental drug poisonings. In prior years, virtually all such deaths were classified as due to drug dependence. New categories were added to various tables to maintain comparability with previously published vital statistics and are continued today. The poisoning codes are added to the natural cause codes in Tables 4, 5, 6, 7, 8, 21 and 25.

! A category of deaths due to accidents without the drug poisoning deaths is used for ranking leading causes and appears in Table 5 and 6. A fuller discussion of the history of drug death coding appears in the Vital Statistics Summaries of 1989 through 1998.

Maternal Death and Maternal Mortality - In ICD-10, the chapter Pregnancy, childbirth and the puerperium (codes O00-O99) includes codes for deaths occurring more than 42 days after the termination of the pregnancy, which did not exist in ICD-9. However, the definition of "maternal mortality" by the World Health Organization does not include these later deaths: included are deaths of a woman while pregnant or within 42 days of termination of pregnancy ... from any cause related to or aggravated by the pregnancy or its management ..." This includes ICD-10 codes O00-O95, O98-O99 and A34, obstetrical tetanus. Note also that the denominator of the maternal mortality rate is live births. Since the 2000 Vital Statistics Summary, new lines have been inserted in Table 4 and Table 25 to clarify the difference.

In Table 4, Deaths by Cause, all deaths due to pregnancy, childbirth and the puerperium are shown (and are rankable) followed by the smaller group of "maternal" deaths. In Table 25, Deaths and Crude Death Rates ...1901-2002, the historical data are correctly relabeled "maternal causes" and a new category, pregnancy, childbirth and the puerperium, is shown beginning in 1999, with ICD-10. In Table 46, Live Births, ... 1986-2002, the difference between the two categories is noted in a footnote, and an error in the 1999 data is corrected. In Table 5, Leading Causes by age, the larger, rankable, cause group appears for age 25-34 in this 2002 Summary.

External Causes of Death - External causes of death include accidents, intentional self-harm (suicide), assault (homicide), legal intervention, events of undetermined intent, operations of war and their sequelae, and complications of medical and surgical care. Beginning in 1999, these causes are shown separately in Table 4.

! Some homicides are considered justifiable and are reported as such by the New York City Police Department under the Uniform Crime Reporting System of the Federal Bureau of Investigation.

! Legal intervention as a cause of death is defined in ICD-10 as including injuries inflicted by police or other law-enforcing agents ... in the course of arresting or attempting to arrest ... and other legal action.

! Complications of medical and surgical care was included with accidents in ICD-9 and is now shown separately.

! All death certificates for external causes are reported by the Office of Chief Medical Examiner. Deaths for which a cause has not been determined by the time the statistical file is closed are shown separately as pending final determination in Table 4; some of these pending deaths will be determined to be due to natural causes. The number has declined since 1989.

! The number of deaths classified as events of undetermined intent has declined since 1989, but they should be considered in analysis of deaths due to external causes.

! The site of accidents, home and public place, has been dropped because the reporting was not reliable.

Fatal Occupational Injuries - The Census of Fatal Occupational Injuries, which provides the data in Table 11 and tables WTC8 and WTC9, is carried out according to a protocol developed by the Bureau of Labor Statistics (BLS) of the U.S. Department of Labor. Autopsy and other reports for deaths due to external causes (see above) are reviewed if the injury occurred at work. Definitions and terminology are those of BLS, which may differ from those generally used in vital statistics. In 2000, a new race/ethnicity

TECHNICAL NOTES, 2002

variable was introduced.

Infant Mortality - The infant mortality rate consists of the number of infant deaths in New York City in a specified year divided by the number of live births in the city in the same year; some infants in the numerator were born in the preceding year, and some in the denominator will die in the following year. The same definition applies to geographic subdivisions included in some tables.

! In this Summary, all characteristics of infant deaths are drawn from the death certificate except in Table 46, which uses the ethnic group of the mother from the child's birth certificate. In Tables 42 and 43, birth weight is based on the birth certificate.

BOROUGH OF RESIDENCE - Borough of residence and other geographic classifications are based on the usual residence reported in the certificate. Since 1985, assignment to geographic areas below borough, such as health center district and community district, is made through the Geosupport Program, developed and maintained by the DCP.

AGE OF DECEDENT - For ages greater than one year, decedent's age is based on age at last birthday. For infants, actual age is used in minutes, hours, days or months. In previous editions of the Summary, if age were unknown it was coded to 65. Beginning with the 2001 Summary, unknown ages are not recoded. There were 16 decedents of unknown age, as shown in Table 3.

PLACE OF DEATH - In reporting Place of Death in Table 9, the term hospital includes residential units, hospices and other special facilities within the hospital. Nursing home includes only sites licensed as Extended Care Facilities by the State of New York. Home refers to the decedent's residence, and includes private houses and apartments, group quarters for special populations, homes for adults, and other long-term residential sites.

PLACE OF BIRTH - Reporting of home births in Tables 32 and 33 has been corrected since 1996 to include events where the certificate was filed through a hospital.

MOTHER'S MARITAL STATUS - New York City is prohibited by local law from recording mother's marital status on the record or report of birth. For purposes of statistical analysis and reporting, it was computed from other information on the birth certificate by coders using an algorithm developed by NCHS, and more recently an algorithm adapted to EBC. In 1996, a review of the results led to the conclusion that the number

of non-marital births was being overestimated. A new method was implemented by an EBC change in 1997.

! The new method uses only the presence or absence of a father's name on the birth certificate and the filing of an acknowledgment of paternity to estimate marital status; a comparison of the surname of the parents was dropped. The new procedure is consistent with that used by New York State.

! More than 91,000 records of 1997 birth certificates were coded using both methods. The overall change in the proportion of unmarried mothers was a decline of 19.2 percent, from 53.2 percent to 43.0 percent. The decline was greater among older women, and varied by ethnic group and type of hospital of delivery as well. These differences contributed to a range of changes across health center districts.

! A complete discussion may be found in the Special Note on Mother's Marital Status in the 1997 Vital Statistics Summary. This characteristic of live births should be analyzed cautiously.

INDUCED TERMINATIONS OF PREGNANCY - Induced Terminations of Pregnancy generally require active surveillance and follow-up to insure complete reporting. As a result, some events from earlier years are included in each year's Vital Statistics Summary. In 1997, one facility was found to have failed to submit reports for over 11,000 1996 procedures. These reports, and about 500 from several other facilities, were reported in revised tables for 1996 pregnancy outcomes in the 1997 Vital Statistics Summary. A discussion of the revised tables and the corrected data for all pregnancy outcomes can be found in the Technical Notes, 1997.

COMMUNITY DISTRICTS -- Community districts were established by City Charter in 1969 for the delivery of city services. Population figures for these districts are compiled by the DCP from census data.

! There are 59 community districts, referred to by their borough and sequence number, compared to 30 health center districts, which have neighborhood names. The number of districts in each system by borough is shown below.

Borough	HCD	CD
Manhattan	7	12
Bronx	6	12
Brooklyn	10	18
Queens	6	14
Staten Island	1	3

There is no translation from one system to the other.

! In establishing population figures for community districts, census totals for counties are kept as borough totals, while the district figures are compiled from census tract and census block

data. Borough boundaries are not always followed, so the sum of the community district populations in each borough does not equal the borough population or the city-wide population.

! The numbers of births and deaths to Manhattan and Bronx residents differ between health center district tables and community district tables because the northernmost Manhattan neighborhood of Marble Hill is in Manhattan under the health center district organization and in the Bronx under the community district system. The population-based rates may change as well. For example, in 2002, 39 deaths were reassigned from Manhattan to the Bronx, as seen in Table 7 and Table 8: the Manhattan death rate for all causes changed from 7.0 per 1,000 population to 6.9, while the rate for the Bronx changed from 7.0 to 7.1 with the addition of the 39 deaths. Rates for the selected causes may change as well. For 2002 births, 118 events were reassigned, as shown in Table 34 and Table 36: the Manhattan birth rate did not change, while the Bronx rate increased from 15.9 to 16.0 per 1,000 population. Eleven births to teenagers were reassigned from Manhattan to the Bronx, seen in Tables 39 and 41: in Manhattan percent of live births to teens decreased from 6.6 to 6.5, while in Bronx, percent of live births to teens remained same, at 12.2.

! The population of Riker's Island, site of New York City Department of Correction facilities, is in the Bronx for health center district purposes and in Queens in the community district system. The small number of vital events to residents have been assigned to Queens in both systems.

! A description of the construction of community district geography can be found in Department of City Planning, Demographic Profiles, DCP # 92-32-Revised, pp. 293-297.

WORLD TRADE CENTER DEATH DATA -- Data are based on 2,746 death certificates registered with the Office of Vital Records through October 31, 2003. The WTC data used in this report are updated from the 2001 Summary to include information from 6 more death certificates filed in the past year. At the time of this report, the official estimate of WTC deaths is 2,752, including 3 deaths that occurred outside New York City. Since the death certificates of three people reported missing have not yet been resolved by the courts, the data are still not final. No decision has been made on the death certificates of hijackers; therefore the information is not included in WTC data.

The categories of occupations and industries in Special Section (World Trade Center disaster deaths) are from the Census of Fatal Occupational Injuries (CFOI), which is conducted by the U.S. Department of Labor, Bureau of Labor Statistics, in cooperation with New York City Department of Health and Mental Hygiene, State, and Federal

TECHNICAL NOTES, 2002

agencies. The definitions are not the same as the ones on New York City death certificates. New York City death certificates ask for usual occupation, the kind of work done during most of a working lifetime and kind of business or industry. But CFOI uses the occupation at the time of the incident or exposure according to the Bureau of Census Occupational Coding System. Industry is the standard industrial classification

code(SIC) of the employer the decedent was working for at the time of the incident or exposure.

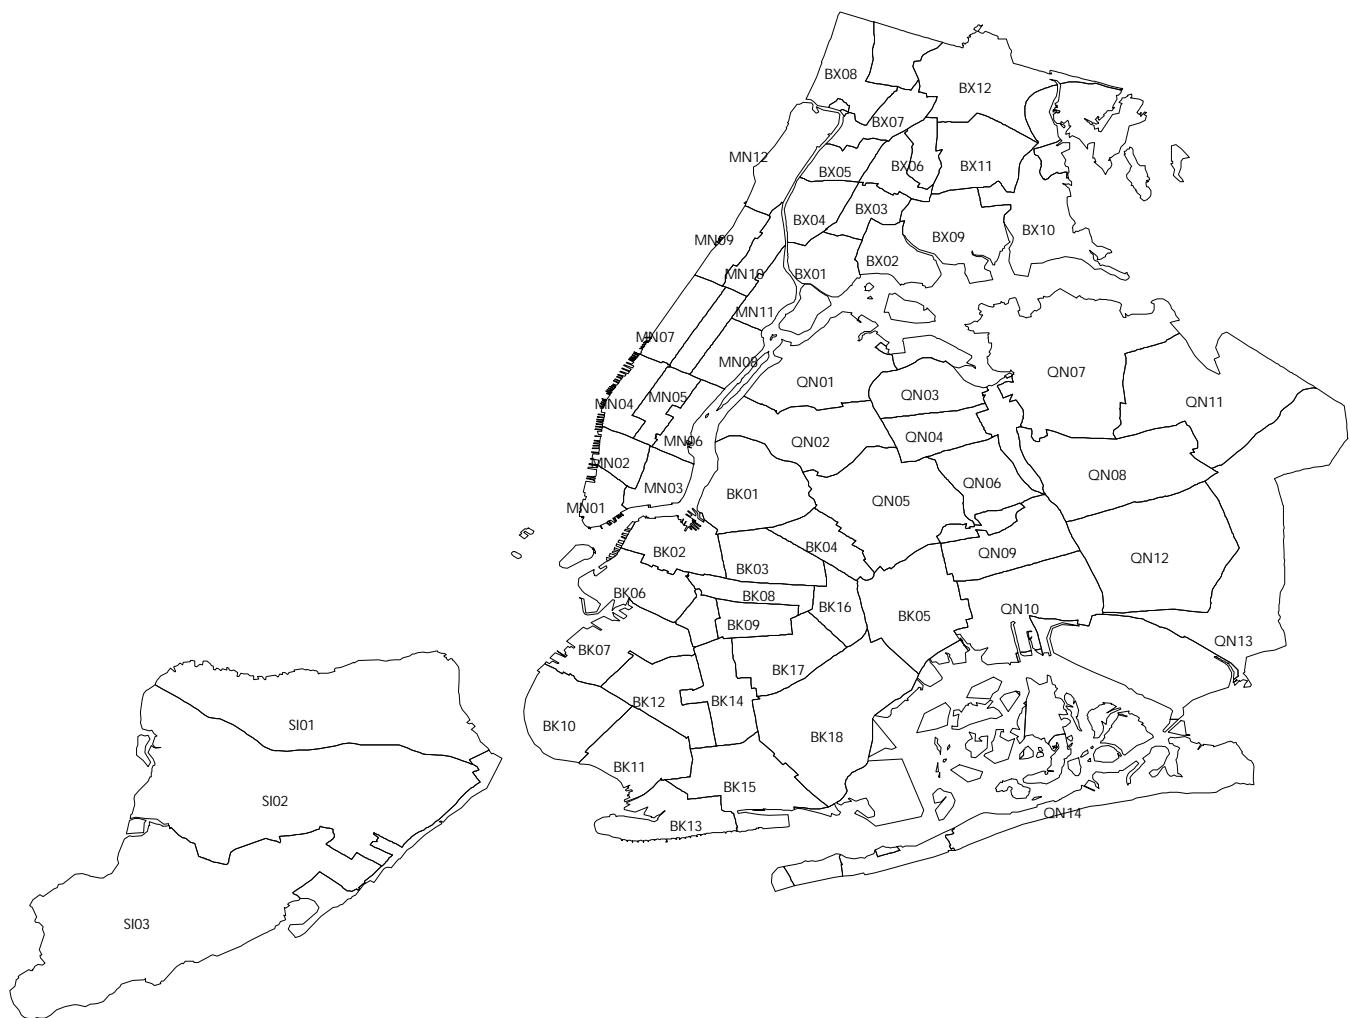

For WTC deaths in table WTC7, New York City has used the CFOI definition where fatal injury meets the CFOI work relationship criteria. Nine death certificates were changed from not at work to at work and 28 cases from at work to not at work according to CFOI's definition.

The total number in Table WTC8 and Table WTC9 includes individuals identified by the Census of Fatal Occupational Injuries even though New York City death certificates have yet been filed, and 3 deaths that occurred outside New York City.

Figure 16. Community Districts and Boroughs, New York City

HIGHLIGHTS, 2002

World Trade Center Disaster - The preliminary data on the deaths caused by the World Trade Center disaster on the morning of September 11, 2001, are presented in a Special Section of this report. The data presented are based on 2,746 death certificates filed with the Office of Vital Records and 3 deaths that occurred outside New York City. At the time of this publication, the official estimate of WTC deaths is 2,752. The Section has been expanded from last year. It includes a new graph that shows no apparent increase or decrease in the number of births nine months after the attack. The Section also includes two tables from the NYC Office of Chief Medical Examiner to show the methods used to identify victims and the status of identification of WTC victims.

West Nile Virus - Twenty nine cases and 3 deaths caused by West Nile Virus (WNV) in 2002 were reported (See Table 4 and Table 47). Among the 29 cases, 19 were male and 10 were female. The median age of the cases was 72 years.

Births and Infant Deaths - The number of live births registered in 2002 decreased 0.9% to 122,937 from 124,023 in 2001, the lowest since 1986. The number of births to teenagers continues to decline in total number, to 9,240, and as a percentage of all live births, to 7.5% (Table 39 - Table 41). This decline mirrors national trends.

The infant mortality rate reached 6.0 infant deaths (under one year of age) per 1,000 live births, the third year of consecutive historic lows. However, the infant mortality rate increased in certain Health Center Districts, such as Pelham Bay, Brownsville, and Fort Greene.

Deaths - The number of deaths in New York City was 59,651 in 2002, another historic low. The death rate for the City also reached an historic low, at 7.4 per 1,000 population. Mean and median ages at death by ethnic group and sex were added to Table 3.

The top three leading causes of death remained the same in 2002, in order: diseases of heart, malignant neoplasms, and influenza and pneumonia. The number of HIV deaths

decreased again, from 1,774 in 2001 to 1,712 in 2002. A new table of leading causes of death by sex for decedents of age less than 65 has been added to this report. The top three leading causes of death for age less than 65 are malignant neoplasms, diseases of heart, and HIV disease. The top three causes among malignant neoplasms (cancer) are trachea-bronchus-lung, breast, and colon-rectum-anus for people who died at age less than 65.

Induced Terminations of Pregnancy - Reported induced terminations of pregnancy in 2002 was 91,800, almost the same as 91,792 in 2001. The number of induced terminations of pregnancy by non-surgical procedures increased 37% from 3,296 in 2001 to 4,519 in 2002, accounting for 5% of all procedure types reported.

Population - The Census Bureau released a modified race file. Therefore, Table 2 was updated following new population data. The major effects are reductions for multiple races and increases for other races. No change for Hispanic origin. See the Technical Notes.

New and Expanded Tables and Figures - The following new tables and figures were added or expanded in the 2002 Summary of Vital Statistics:

- Figure 1. Number of deaths from selected causes, age < 65, 1983-2002;
Tables 5 and 6.
Expanded to include totals, in addition to male and female;
- Table 5a. Leading causes of death by sex, age < 65, 2002;
Table 6a. Leading causes of death in specified ethnic groups by sex, age < 65, 2002;
- Table 49. Expanded to include infant deaths;
- Table 52. Live birth by borough and institution, 2002;
- Figures 5 and 6.
Split to show natural causes and external causes separately and to add a few more causes;
- Figure 11. Number of live births, induced terminations, and spontaneous terminations, 1983-2002.
